Social Network Analysis

This is a report generated from social network analysis of the actors within the shrimping industry on the Georgia Coast. The resulting output of the analysis demonstrates the relationships between shrimpers, dockers, and other agencies/organizations.

Network attributes

- Diameter

The network has a diameter of 12. This measure is the length of the longest geodesic (the largest distance between any two vertices in a connected graph).

- Reciprocity

The network has a reciprocity of 0.0604633. The measure of reciprocity defines the proportion of mutual connections, in a directed graph.

- Number of edges The network has 2547 total edges.
- Number of egos The network has 592 total egos
- Edge density

The network has a density of 0.0072798. This measure is the ratio of the number of edges and the number of possible edges.

- Transitivity

The network has a transitivity of 0.0914083. This measure is the probability that the adjacent vertices of a vertex are connected. This is sometimes also called the clustering coefficient.

Vertex attributes

- Closeness

The vertex with the greatest closeness is *Lewis, Eunice* (number: 332). This measures how many steps is required to access every other vertex from a given vertex.

The vertex with the least closeness is *Yourell, Amy* (number: 303). This measures how many steps is required to access every other vertex from a given vertex.

- Degree

The vertex with the greatest degree is *Mirmortazavi, Bridgette* (number: 228). This measure is the number of its adjacent edges.

The vertex with the fewest degree is *Palomo, Daianaira* (number: 521). This measure is the number of its adjacent edges.

Network plots

Figure 1: Original social network plot with no alterations (Fruchterman-Reingold layout)
